

Meningococcal Disease is caused by the bacterium *Neisseria meningitidis* (meningococcus) and is a normal inhabitant of the human nasopharynx. It is transmitted from person to person by aerosol, droplet and direct spread. Up to 10% of adults are colonised at any time and develop no signs or symptoms of disease. There are five main meningococcal serotypes (A, B, C, W, and Y) that can cause disease in humans. Meningococcus can cause invasive disease, including meningitis and septicaemia and is most common during the winter months. Young children and teenagers are at highest risk of meningococcal disease
